DOI: 10.29252/ijop.13.2.119

**ABSTRACT—** In this paper, we proposed an all optical 4-to-2 encoder that has 4 input and 3 output ports. This device generates a 2 bit binary code based on which input port is active. We used nonlinear photonic crystal ring resonators along with optical power splitter for realizing the proposed encoder. In this device the switching rate and area are obtained about 333 GHz and  $612\mu\text{m}^2$  respectively.

**KEYWORDS:** Kerr effect, Optical encoder, Photonic bandgap, Photonic crystal.

## I. INTRODUCTION

Optical logic devices are important building blocks that can be used in all optical networking and optical signal processing. High speed and high band width are the major benefits of optical networks and optical signal processing [1]. In order to avoid undesirable delays imposed by conversion from electrical to optical and optical to electrical in optical networks, we need all optical networks in which all process is done in optical form [2]. The main prerequisite for realizing all optical networks is to have all optical devices. Optical logic devices such as optical logic gates, decoders, multiplexers and encoders are the fundamental elements in optical logic circuits used for optical signal processing.

Optical encoder is a logic device that has  $2^N$  input and N output ports. Optical encoder generates an N bit code based on which input port is active. Beside their applications in optical signal processing systems, optical encoders are one the main building blocks in all optical analog to digital converters (ADCs). In realizing optical ADCs after creating

discrete levels of input analog signal, we need an optical encoder to convert the discretized levels of input analog signal into standard binary codes [3-5].

Photonic crystals (PhCs) can be used for designing all optical devices. Periodic distribution of refractive index in these structures results in photonic band gap (PBG), with which they can control and confine the propagation of optical waves inside very compact dimensions [6]. PhC based devices are scalable and very flexible. Therefore, by changing lattice constant or other structural parameters of the structure it is possible to easily control the optical behavior of the device [7-9].

Due to these properties, it has been shown that PhCs are suitable for designing many optical devices such as optical filters [10-14], demultiplexers [15-17], switches [18-20], logic gates [21-24], and decoders [25-27].

Moniem [28] proposed an all optical 4-to-2 digital encoder, in which he combined 4 resonant rings with T-waveguide to design the proposed encoder. The switching speed and area of this encoder are 500 GHz and  $1225\mu\text{m}^2$  respectively. By combining elliptical ring resonators and PhC waveguides, Hassangholizadeh-Kashtiban *et al.* proposed an all optical 4 to 2 reversible encoder [29]. The area of this structure is  $217\mu\text{m}^2$ . Alipour-banaei *et al.* [30] proposed another optical encoder by combining self-collimation effect of PhC structures with power splitters and reflectors, in which the lattice constant is  $1\mu\text{m}$ , which results in a large area ( $3795\mu\text{m}^2$ ).

Also its performance is very sensitive upon the phase of input light. They reported response time as long as 1.4 ps for their presented structure.

In this paper, we aim to design a compact all optical 4-to-2 optical encoder whose area and switching speed are suitable for employing in optical integrated circuits (OICs). For this purpose, we will combine nonlinear Kerr effect with PhC ring resonator structure. We used plane wave expansion (PWE) and finite difference time domain (FDTD) methods [31, 32] for analyzing and simulating the proposed structure and obtaining its optical behavior.

The rest of the paper is organized as follows: in section 2 we will propose the basic photonic crystal ring resonator based switch structure used for designing the encoder, in section 3 we are going to discuss the design procedure and simulation results of the optical encoder and finally in section 4 we will conclude from our work.

## II. FUNDAMENTAL SWITCH

For realizing the proposed 4-to-2 optical encoder we need to design a fundamental switch. The basic PhC platform used for designing the optical switch is a  $29 \times 23$  array of silicon rods with square lattice in the  $z$  and  $x$  directions. The rods are oriented along the  $y$ -axis. The refractive index and radius of the dielectric rods are  $n=3.46$  and  $r=0.2 \cdot a$  respectively, where  $a=600$  nm is the lattice constant of the structure.

Figure 1 shows that this structure has three PBG regions and we choose the one with the largest width, which is at  $0.28 < a/\lambda < 0.41$  in TM mode which are equal to  $1463 \text{ nm} < \lambda < 2142$  nm. In this mode,  $z$ -component of the magnetic field is zero. Blue and red colors indicate TM and TE modes in band structure respectively.

The fundamental switch is composed of two parallel optical waveguides and a nonlinear resonant ring which is sandwiched between these waveguides. In the proposed switch, the

upper and lower waveguides are called bus and drop waveguides respectively. As shown in Fig. 2a, the fundamental switch has four ports labelled as A, B, C and D. Port A is the input port and B, C and D are forward transmission, backward drop and forward drop ports. Around the core we put 24 rods made of doped glass, which are shown via green color in Fig. 2(a). The linear refractive index and Kerr coefficient of the doped glass are  $n_0=1.4$  and  $n_2=10^{-14} \text{ m}^2/\text{W}$  [5]. The variation of normalized light intensity at the output ports of the proposed switch is shown in Fig. 2(b).

Fig. 1. The band structure of the fundamental PhC.

Fig. 2. (a) The schematic and (b) the normalized light intensity at output ports of the fundamental switch.

One can see that for lower optical intensities the port B is OFF, and by increasing the input intensity it will turn ON gradually. In this paper the normalized threshold required for the output ports to be considered ON (i.e. Logic 1) is set to be 0.4, also optical intensities less than 0.1 normalized value will be considered OFF (i.e. logic 0). The resonant rings include the nonlinear rods whose refractive indices are depend on the launched optical power in the ring. This issue results in changing power loss for different optical power. So, the difference of the intensity summation in both ends of the device is occurred.

Distribution of optical waves inside the switch for two different optical intensities are shown in Fig. 3. For optical intensity less than  $0.2 \text{ KW}/\mu\text{m}^2$ , most of the optical waves will drop into drop waveguide and travel toward port C, however for optical intensities more than  $1.2 \text{ KW}/\mu\text{m}^2$  most of the optical waves will travel toward port B.

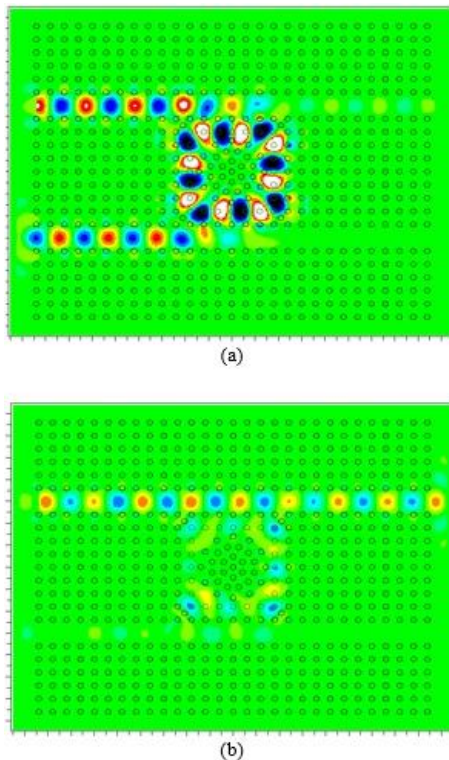

Fig. 3. Distribution of optical waves inside the structure for (a) Low and (b) High input optical power intensities.

This phenomenon is due to the Kerr effect and refractive index dependency of the PhC

structures optical behavior. When the optical power intensity is low, the central wavelength of the input light coincides with the resonant wavelength of the resonant ring, so the ring will drop light waves into drop waveguide. However, when the optical power intensity reaches to the threshold value, the variation of the refractive index of the dielectric rods, will shift the resonant wavelength of the resonator so that the central wavelength of the input light will not coincide with the resonant wavelength of the resonator. Therefore, the input light will not be dropped into drop waveguide and will travel toward port B.

### III. OPTICAL ENCODER

The fundamental PhC platform employed for designing the proposed encoder is a  $35 \times 50$  array of dielectric rods with square lattice. The structural parameters such as refractive index, radius and lattice constant are the same as the proposed switch. So the band structure diagram and PBG region will be the same too.

The proposed optical encoder is composed of three optical waveguides – namely  $W_1$ ,  $W_2$  and  $W_3$  –, two ring resonators – namely  $R_1$  and  $R_2$  – and an optical power splitter, as shown in Fig. 4. By removing 3 complete rows of dielectric rods the waveguides were created at the appropriate locations inside the fundamental platform. The power splitter is simply created by combining two waveguides with a T-branch structure. The power splitter has two branches – namely upper and lower branch – that are labeled with PSU and PSL respectively.

The first ring resonator ( $R_1$ ) is placed between  $W_2$  and PSU and the second ring resonator ( $R_2$ ) is placed between  $W_3$  and PSL. The proposed encoder has four input ports and three output ports. The input ports are labeled with  $I_0$ ,  $I_1$ ,  $I_2$  and  $I_3$ . The output ports are labeled with V,  $O_1$  and  $O_2$ .  $O_1$  and  $O_2$  are the binary output ports and V is used for distinguishing the completely OFF state of the encoder from the state in which  $I_0$  is active. The power splitter is designed completely symmetrical so that, it splits the optical

intensity coming from port  $I_3$  into 2 identical parts.

After finalizing the design procedure, we are going to simulate the proposed structure and study its optical behavior. For this purpose, we employed optical waves with  $\lambda=1550$  nm and optical power intensity of  $P_0=0.7$  KW/ $\mu\text{m}^2$  at each input port. We have to mention that the required threshold for the output ports to be considered ON is 0.4 normalized power. The working states of the encoder are as follows:

Fig. 4. The final sketch of the proposed encoder.

State 1: When all input ports are OFF (i.e.  $I_0=I_1=I_2=I_3=0$ ) which is shown in Fig. 5(a) all the output ports will be OFF, and the encoder generates "00" at the output ports and  $V=0$ .

State 2: When  $I_0=1$  and  $I_1=I_2=I_3=0$ , which is shown in Fig. 5 (b), the optical power entering the structure from  $I_0$  will propagate in  $W_1$  and travel toward port  $V$ , and will not reach to  $O_1$  and  $O_2$ . So that  $V$  will be ON and  $O_1$  and  $O_2$  will be OFF (i.e.  $V=1$ , and  $O_1=O_2=0$ ). The normalized power intensity at port  $V$  will be about 95%. When  $I_0$  is ON the encoder produces "00" binary code at the binary output ports. For both state 1 and state 2,  $O_2O_1=00$  therefore using port  $V$  one can distinguish these states. On the other hands, if no input is applied to the device, port  $V$  will be OFF and shows  $O_2O_1=00$  is due to no input signal and

device is inactive. However, port  $V$  will be ON for  $I_0=1$  and  $I_1=I_2=I_3=0$  and shows one of the input ports ( $I_0$ ) is active.

State 3: when  $I_1=1$  and  $I_0=I_2=I_3=0$ , which is shown in Fig. 5(c), the optical waves entering the structure from  $I_1$  will propagate inside  $W_2$  and travel toward  $R_1$ . As discussed in section 2 when optical intensity is about  $0.7$  KW/ $\mu\text{m}^2$ ,  $R_1$  cannot drop all of the light waves from  $W_2$  into  $PSU$ , so that the great portion of the light waves will travel toward port  $O_1$  but there is no optical power at  $O_2$ . The normalized light intensity at port  $O_1$  and  $O_2$  will be about 51% and 1% respectively. Therefore, in this case  $O_1$  is ON and  $O_2$  is OFF and encoder generates "01" binary code at the output ports. In this case  $V$  is OFF.

State 4: when  $I_2=1$  and  $I_0=I_1=I_3=0$ , which is shown in Fig. 5(d), the optical waves entering the structure from  $I_2$  will propagate inside  $W_3$  and travel toward  $R_2$ . As discussed in section 2 when optical intensity is about  $0.7$  KW/ $\mu\text{m}^2$ ,  $R_2$  cannot drop all of the light waves from  $W_3$  into  $PSL$ , so that the great portion of the light waves will travel toward port  $O_2$  but there is no optical power at  $O_1$ . The normalized power intensity at port  $O_1$  and  $O_2$  will be about 1% and 51% respectively. In this case  $O_1$  is OFF and  $O_2$  is ON and encoder generates "10" binary code at the output ports. In this case  $V$  is OFF.

State 5: when  $I_3=1$  and  $I_0=I_1=I_2=0$ , the optical signals entering the structure from  $I_3$  will be divided into 2 identical parts by the power splitter, one part propagates inside  $PSU$  and travel toward  $R_1$ , and the other part propagates inside  $PSL$  and travels toward  $R_2$ . Therefore, the amount of optical power intensity near each resonator will be about  $0.35$  KW/ $\mu\text{m}^2$ . So according to Fig. 2(b),  $R_1$  and  $R_2$  can drop the light waves from  $PSU$  and  $PSL$  into  $W_2$  and  $W_3$  respectively, so that light waves will travel toward  $O_1$  and  $O_2$ . The normalized power intensity at both  $O_1$  and  $O_2$  ports will be about 43%. Therefore, in this case  $O_1$  and  $O_2$  are ON and encoder generates "11" binary code at the output ports. In this case  $V$  is OFF. This is shown in Fig. 5(e).

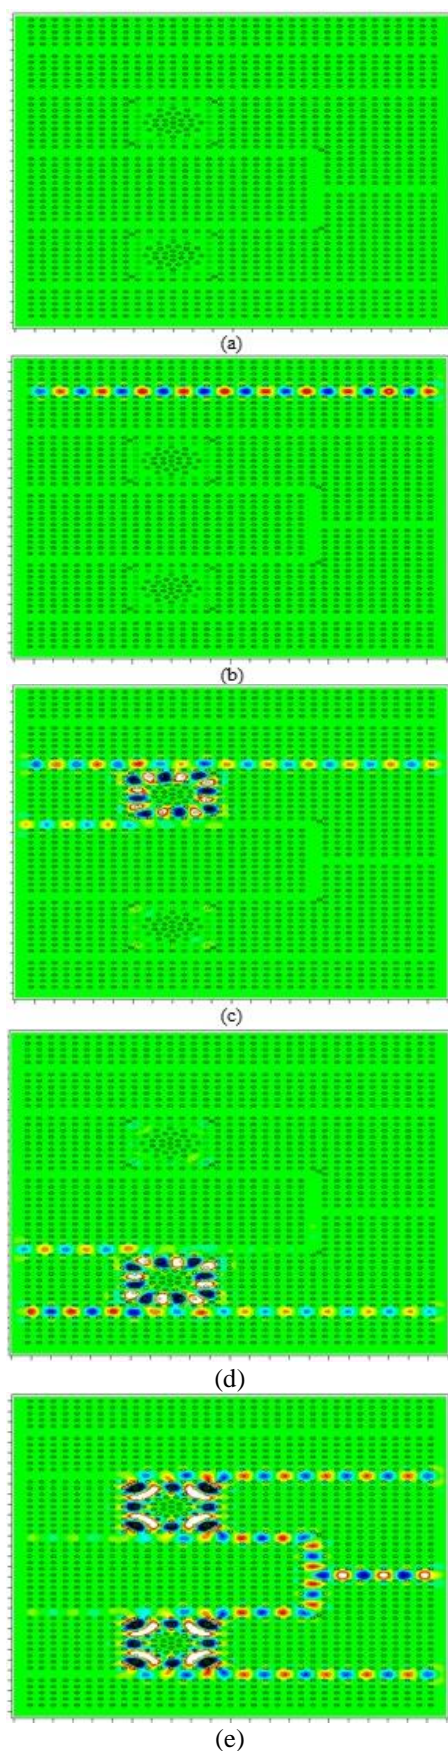

Fig. 5. The working states of the proposed encoder, (a)  $I_0=I_1=I_2=I_3=0$ , (b)  $I_0=1$  and  $I_1=I_2=I_3=0$ , (c)  $I_1=1$  and  $I_0=I_2=I_3=0$ , (d)  $I_2=1$  and  $I_0=I_1=I_3=0$ , (e)  $I_3=1$  and  $I_0=I_1=I_2=0$ .

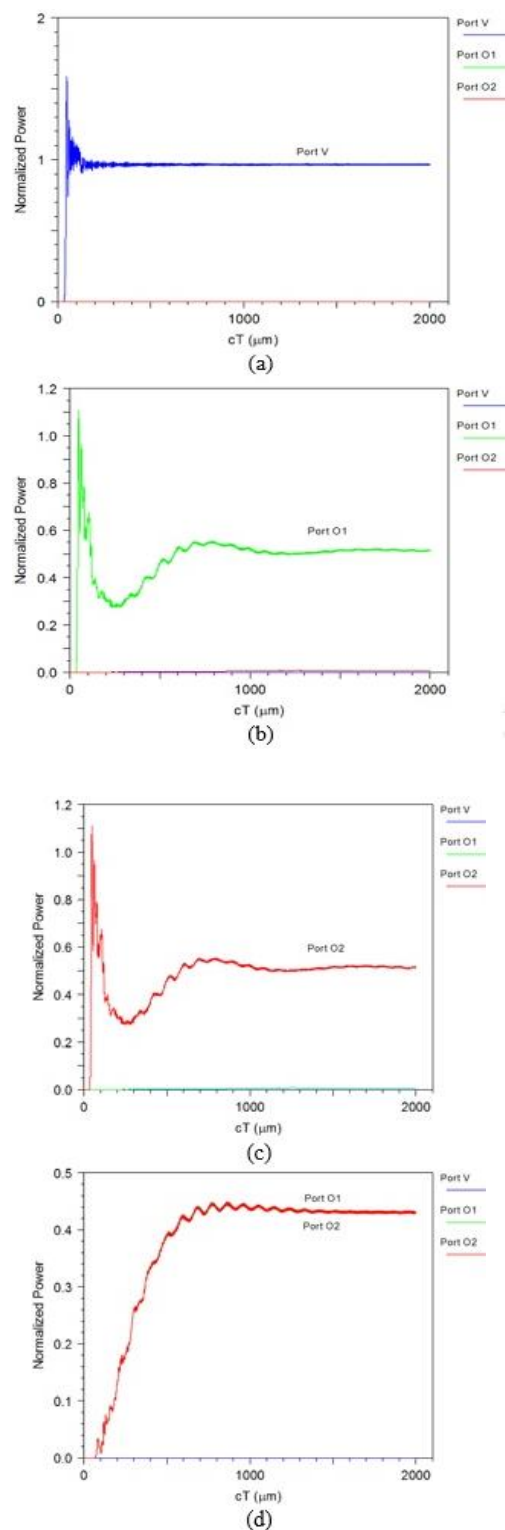

Fig. 6. The time response of the structure for different states (a)  $I_0=1$  and  $I_1=I_2=I_3=0$ , (b)  $I_1=1$  and  $I_0=I_2=I_3=0$ , (c)  $I_2=1$  and  $I_0=I_1=I_3=0$ , (d)  $I_3=1$  and  $I_0=I_1=I_2=0$ .

Figure 6 shows the time response of the proposed structure, in these diagrams the vertical axis represents the normalized power at the output ports and the horizontal axis shows the “cT” parameter in “ $\mu\text{m}$ ”, by

dividing the values of the horizontal axis into  $c=3 \times 10^8$  m/s, one can obtain the time values in second. According to Fig. 6 the delay time for the aforementioned working states are  $t_i=0.05$ , 3, 3, and 2.5 ps (where  $i=2, 3, 4$ , and 5 represents the different working states discussed above).

As shown in Figs. 6(a-c), the normalized power exceeds 1. This issue is due to the resonance phenomenon in both rings. Haus presented a transmission line method based on LC (or second order) circuit for light propagation in cavity and ring resonators [33]. He demonstrated the constructive interferences could be related to the resonance phenomenon. As far as we know the overshoot can be occurred at underdamped case of a second order circuit.

The maximum delay time for the proposed structure is about  $t=3$ ps, so that the switching rate of the proposed encoder will be about 333 GHz. These states are summarized in Table 1 and are shown schematically at Fig. 6.

As shown in Table 1 for the proposed structure one can distinguish state 1 (i.e.  $I_0=I_1=I_2=I_3=0$ ) from state 2 (i.e.  $I_0=1$  and  $I_1=I_2=I_3=0$ ). The total area of the proposed structure is about  $612 \mu\text{m}^2$ .

In order to evaluate the presented device, a comparison between this work and others [28-30] is presented in Table 2. Maximum response time and overall area of the structure are denoted with  $T_{\text{res}}$  and Area respectively. One can see the proposed device is more compact than Ref [28, 30]. Although in Ref [30] the low response time is obtained, using self-collimation effect results in more sensitivity rather than the proposed structure in this work. In addition, large area is taking account as an important disadvantage for Ref [30]. Contrast ratio between the normalized power margins for logics 1 and 0 is a significant issue in designing all optical devices. Table 1 demonstrates that this parameter is obtained as large as 0.42 for the proposed device. The calculated value for the mentioned ratio is more than obtained ratio in

Ref [29] (0.35) and is suitable for light coupling from output ports to other devices. With regard to the obtained results, the presented structure can be proposed for using in optical integrated circuits.

Table 1. All working states of the device.

Inputs				Outputs					
				Normalized Output Power			Logic Level		
$I_0$	$I_1$	$I_2$	$I_3$	V	O2	O1	V	O2	O1
0	0	0	0	0	0	0	0	0	0
1	0	0	0	0.95	0	0	1	0	0
0	1	0	0	0	0.01	0.51	0	0	1
0	0	1	0	0	0.51	0.01	0	1	0
0	0	0	1	0	0.43	0.43	0	1	1

Table 2. Comparison between obtained results in this study and other works.

This work	3	612

## IV. CONCLUSION

In this paper we proposed an all optical 4-to-2 encoder, using 2D PhC structures. The proposed structure was realized by combining optical waveguides, ring resonators and power splitter. The maximum rise time and switching rate were obtained about 3ps and 333 GHz respectively. The overall area of the proposed structure is about  $612 \mu\text{m}^2$ . The proposed structure can generate a 2 bit binary code according to which input port is active.
