DOI: 10.29252/ijop.13.2.189

**Abstract**— stabilized Ag Nanoparticles (NPs) were synthesized using Lee-Meisel method under three different conditions in an oil bath. UV-Vis spectroscopy of the Ag NPs showed a Localized Surface Plasmon (LSP) band around 430 nm, indicating Ag NPs had a size range around 40 nm. To fabricate a surface Enhanced Raman Spectroscopy (SERS) substrate, LSP properties of Ag NPs was employed with the goal of detecting Rhodamine 6G dye. SERS spectrum was recorded by using 180 degrees, back-scatter Raman configuration in a custom-made mount. The results showed that ideal Ag NPs agglomeration condition had been achieved by applying centrifuging process and due to this, adding NaCl salt to the SERS substrate was found to be unnecessary. The optimum rate of tri-sodium citrate versus silver nitrate and its influence on UV-Vis and SERS spectra was determined. It was understood that in order to obtain a uniform SERS intensity profile, employing a heater-stirrer instead of an oil bath alongside controlling the atmospheric condition and also drying the substrate in the Argon gas medium are the most necessary conditions for Ag NPs synthesize. The novelty point is obtained when SERS of R6G on a certain substrate, immediately after fabrication and after one month, were compared with a bare R6G dye substrate which, have revealed exceptional performance.

**Keywords:** SERS, Ag NPs, Lee-Meisel, LSP

## I. INTRODUCTION

Nanomaterials are different from their bulk counterparts in various features like electronic, magnetic, stress and strain properties. Metal nanostructures especially transition metal nanoparticles have been excessively invested in the fields like nanocatalysts, biosensing and etc. [1]. Transition metals show exceptional properties. When a transition metal with specific condition is exposed to a certain wavelength of light, collective oscillation of electrons provokes localized high electromagnetic field zones called Localized Surface Plasmon Resonance (LSPR). Transition Noble metal nanostructures exhibit surface enhanced Raman scattering, throughout which, Raman scattering cross section of the molecules (analyte) adsorbed onto the metal nanostructure increases significantly. Since attenuation lines of silver exceed that of gold, and Plasmon resonance enhancement of it is greater, silver is preferred over gold. SPR band of silver could be set to all the visible wavelength of light and also, silver NPs cost much less than gold NPs. Disadvantageous to these features, mobility of Ag ions is fast and Ag ions oxidize easily [2&3]. While these properties strongly affect the uniformity of SERS intensity and its

reproducibility, the controllable synthesis of Ag NPs is still a challenge [4]. SERS is employed to detect different materials from biological to environmental analytes [5]. The Raman weak cross section limits its application, so the analyte molecules should be located in close proximity of plasmonic nanostructure [6] & [7]. If nanoparticles have had a constant size distribution throughout the SERS sample and have been sufficiently close to each other, a strong interaction between the nanoparticles and analyte molecules would be gained [8]. Since there is no adequate and unique substrate, SERS is limited to each analyte where for each, a specific substrate has to be employed [9].

In this research, in order to unify the SERS intensity of dye molecules, Ag NPs were synthesized in three different conditions. Ag NP SERS substrate and Ag NP plus NaCl salt SERS substrate were fabricated to detect R6G dye Raman signal. Also, the effect of time and concentration of Ag NPs on Raman Intensity of R6G were investigated by employing UV-Vis spectroscopy and SERS.

## II. EXPERIMENTAL PROCEDURE

### A. Material and Methods

AgNO<sub>3</sub>, tri sodium citrate, Ethanol, Acetone were provided from sigma Aldrich. All of the chemical reagents were used as received. Deionized water was used in all experiments. In the beginning, all of the lab glassware were washed with chromic acid, and then rinsed with deionized distilled water several times.

### B. Ag NP Synthesis

Stabilized Ag NPs were synthesized using Lee-Meisel method in an oil bath [10&11]. An aqueous solution with 0.5 mM AgNO<sub>3</sub> was heated while stirring in the oil bath. In order to have a constant temperature, it was controlled in the reaction medium using a laser thermometer. Humidity was controlled using a cooling system. After that, 0.5 mM aqueous solution of tri sodium citrate, with a 99% purity and 294.10g/M molar mass was

simultaneously stirred while heating and then it was combined with the boiling solution of silver nitrate at once. The reaction was continued at the boiling temperature for one hour with stirring alongside controlling humidity. At the end of reaction, it was allowed to cool to room temperature. At last, multiple centrifuging, and rinsing processes were followed.

Table 1. Nanoparticle and SERS Samples

	Sample Numbers	Description
Samples of Nanoparticles	S.N. 1	Ag NPs synthesized in oil bath and then centrifuged
	S.N. 2	T:A-R: 3
	S.N. 3	T:A-R: 4.5
	S.N. 4	Ag NPs synthesized in oil bath, no centrifuging followed
	S.N. 5	Ag NPs synthesized using heater-stirrer, Ar gas
SERS Samples	S.S.1	R6G+Ag NPs
	S.S. 2	R6G+NaCl+Ag NPs
	S.S. 3	R6G+S.N. 2
	S.S. 4	R6G+S.N. 3
	S.S. 5	R6G+S.N. 1
	S.S. 6	R6G+S.N. 4
	S.S. 7	R6G+S.N. 5

### C. Fabrication of SERS Substrate and SERS Setup

The glass slides were cut into 4 cm<sup>2</sup> pieces and then washed with ethanol, acetone and distilled water, respectively. After that, SERS samples were prepared to investigate R6G SERS detection. Ag NPs were drop cast onto the glass substrate and it was allowed to dry in room condition. At last, R6G dye with a 0.1 mM concentration was deposited onto the glass piece. Fabrication of the S.S.2 was the same, except that, it carried with itself ratio of 1:1 Ag NP: NaCl salt.

Schematic SERS layout is shown in Fig. 1. At first, The second harmonic CW (Nd:YAG) laser with 20 mW pass through the band pass filter (FL532-10), and is split by dichroic beam separator Di02-R532. Next, the reflector element is sending the laser beam to the lens and then to the sample (it was held with sample holder) it enters the spectrometer.

Scattered beam from the sample is collected using ICCD istar (HD334) and then it transmits through the band stop filter (NF533-17), to enter the spectrometer (Ocean Optics HR4000CG-UV-NIR), which collects the sample traces.

Fig. 1. SERS Schematic layout: 1 Laser, 2 Band pass filter 3 Sample, 4 Dichroic beam Separator, 5 Band stop filter, 6 Fiber, and 7 Spectrometer

### III. RESULTS AND DISCUSSION

UV-Vis of S.N. 1 is shown in Fig. 2. In this figure, two shoulders were shown at 404 nm and 428 nm attributed to the Ag NP with 40-50 nm size range. We found this Particle size distribution similar to the experimental and simulation results which was obtained by Shen, *et al.* [4, 14-16], for silver and gold respectively. The UV-Vis and SEM shown in Fig. 3 proved this as the desired size of Ag NPs for SERS measurements, was proved by [4].

Fig. 2. UV-Vis absorption of sample S.N.1.

FE-SEM image of S.N. 1 shown in Fig. 4 presents spherical profile and homogeneous distribution for Ag NPs. It also determines a size range of 30 to 40 nm for Ag NPs synthesized in the oil bath.

SERS signal of S.S.1 and S.S. 2 (R6G plus Ag NPs and R6G plus NaCl plus Ag NPs, respectively) are presented in Fig. 5. It is clear that absence of NaCl positively affected the Raman spectrum of R6G. Appropriate agglomeration produces a desired SERS intensity [17] which was obtained through several centrifuging processes.

Fig. 3. (a) UV-Vis spectra and (b) SEM images of 28 to 75 nm Ag NPs [4].

Increased adsorption of dye pigments due to more vacant positions around Ag NPs have resulted in improved SERS signal in S.S. 1. Stronger fluorescent observed in the original graph (not shown here) is a proof for this conclusion.

(a)

(b)

Fig. 4. (a) Image of Ag NPs size distribution and (b) The exact size measured by FE-SEM for synthesized Ag NP.

In S.S.2, SERS intensity dropped due to decrease in the appropriate hot sites and absorption of R6G molecules. This is caused by aggregation of R6G dye and big clusters of Ag NPs created by the addition of NaCl salt. Also we claim that, for the first time, the detection of R6G SERS was observed for peaks located at 354, 851, 979.03 and 1072.17, are shown in Table 2 and in Fig. 4.

Fig. 5. SERS of S.S.1 and S.S.2.

Table. 2. Comparison of experimental and literature values of different vibrational modes of R6G.

Vibrational modes of functional groups	Literature values (cm <sup>-1</sup> ) [18, 19, 20]	Experimental Values (cm <sup>-1</sup> )
$D_{2h}^{15}$ symmetric group frequency	-	354
C-H out of plan bend	785 [18]	727
Ring breathing vibration	-	851
	-	979.03
	-	1072.17
$D_{2h}^{15}$ symmetric group frequency	1186.9 [18]	1148.12
C-H out of plan bend	1303 [18, 19]	1266
Ring breathing vibration	1357 [18, 19]	1324
Aromatic C-C stretching	1508 [18, 19]	1468
	1647 [18, 19]	1598

#### IV. THE EFFECT OF TRI-SODIUM CITRATE / $\text{AgNO}_3$ RATIO

Ag NP synthesis was repeated using different Tri-sodium citrate:  $\text{AgNO}_3$  Ratio (T: A-R) to provide for SERS substrate reproducibility and investigate the effect of tri sodium citrate on the nanoparticle size distribution. UV-Vis of S.N.2 and S.N.3, and SERS of S.S. 3 and S.S. 4 are presented in Fig. 6 and 7. Table 1 includes descriptions of the samples.

Fig. 6. Comparison between UV-Vis spectra of S.N.2 and S.N.3.

A slight blue shift is observed for the higher T: A-R (S.N. 3) in Fig. 6 (UV spectrum), which is caused by the decrease in the Ag NPs size. Increase in the number of tri sodium citrate molecules, limits the  $\text{Ag}^+$  ions to attach to the Ag nuclei, so a smaller size is gained.

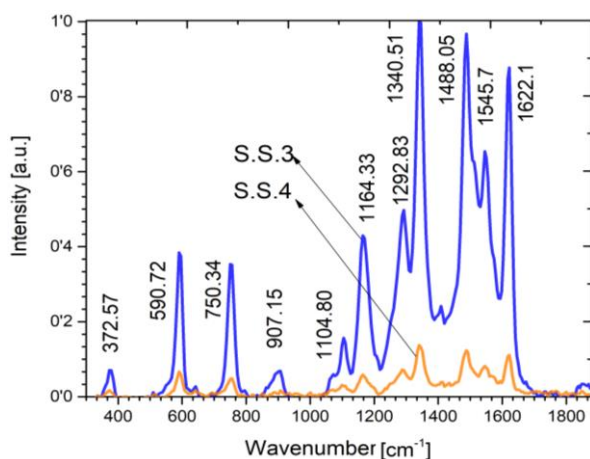

Fig. 7. Comparison of SERS spectra of S.S. 3 and S.S. 4.

The smaller Ag NPs in S.N. 2 could not compete with the bigger ones in S.N. 3 in terms of SERS spectra. An intensity ratio over 4 times is observed for S.N. 2. Comparison between Fig. 6 and 7 verify the dependence between UV-Vis and SERS spectra.

#### V. THE EFFECT OF CENTRIFUGING AND RINSING

S.N. 1 was synthesized the same way mentioned in the experimental section. But S.N.4 was processed without followed centrifuging.

Fig. 8. UV-Vis spectra of S.N. 1 and S.N. 4.

UV-Vis spectra of these samples, is shown in Fig. 8 which presents a Gaussian spectrum, single plasmon peak and a smaller FWHM band for S.N.1. On the contrary S.N. 4 shows unwanted additional peaks at 360 nm, 406 nm, and 476 nm which intervene with the plasmon band, hides it and broaden the FWHM band of the Ag NPs. Because band width of S.N. 1(80 nm) and S.N. 5 overlap in similar intensities, the chance of size distribution being around 40 to 50 nm is high.

Figure 9 describes SERS of S.S.1 versus S.S.5. Size distribution difference between S.N. 1 and S.N. 4 presented itself through decrease in SERS intensity. So, SERS spectrum was affected by nanoparticle size distribution.

Compared with UV-Vis analysis, it shows a smaller noise which proves that SERS is not as affected by the extra salts synthesized during reaction.

Fig. 9. SERS spectra of S.S. 5 and S.S. 6.

a very capable Raman enhancer. SERS intensities obtained shows a 0.72 to 1 ratio which is a promising for unification of SERS throughout samples.

Fig. 10. UV-Vis spectrum of S.N. 5.

## VI. SERS SUBSTRATE OPTIMIZATION

When an oil bath is employed in the fabrication of Ag NPs, un-uniform SERS spectrum is observed [12]. If medium is filled with oxygen around the reaction flask, the possibility of having a few oxidized Ag NPs and an inhomogeneous Ag NP colloid increase. This would cause lack in single size distribution and distorted adsorption of analyte molecules onto the Ag NPs and excites different localized surface Plasmon resonance modes which dampen the SERS signal [13].

To reach an optimum condition for Ag NPs synthesis, instead of the oil bath, the magnetic heater was used along with stirring to obtain positive results. Reaction atmosphere was deployed of oxygen by flowing argon gas with 100 mbar pressure. If  $\text{Ag}^+$  is exposed to light, it shows great tendency to graft with oxygen ions. To avoid this effect, we isolated reaction flask with a thick aluminum foil, also creating a cavity that reflect the heat back into the flask.

Figure 10 shows UV-Vis spectrum of S.N. 5. Figure 11 shows SERS spectra of S.S. 7. It is seen that each point of SERS substrate acts as

Fig. 11. SERS spectra at different positions of S.S. 7.

Considering the drop-cast method used to fabricate SERS substrate, these results qualifies our method of Ag NP synthesis and it creates a path for our future researches.

## VII. DETERMINING THE LIFE TIME OF SERS SAMPLE

With the goal of researching an optimum life time for our SERS samples were tested S.S. 7 sample immediately after fabrication and one month after. Also to compare the results,

Raman spectrum of bare R6G is given. Fig. 12 shows SERS response of S.S. 7 compared with its older version and a bare R6G substrate. SERS without Ag NPs shows only perturbation. Raman spectrum of R6G is difficult to detect because of its strong fluorescence. When SERS spectrum is collected right after substrate fabrication, it shows Raman peaks of R6G, not the background noise appeared in the case of bare R6G. Even after one month, SERS substrate was significantly capable of detecting the analyte.

Fig. 12. Determination of life time of S.S. 7.

## VIII. CONCLUSION

SERS sample with and without NaCl salt with ratio of 1:1 for the sample containing salt was fabricated.

The effect of Ag NPs size distribution, the synthesize root and the time interval on SERS and UV spectra was investigated.

The novelty and significant points were obtained as:

- The effect of size on UV-Vis are investigated which compared to the review literature, was found to be compatible with the FE-SEM and SERS observations.
- The SERS substrate without NaCl salt has given the outstanding results.

- The peaks at 354, 851, 979.03 and 1072.17 were detected by SERS for the first time.
- Single size NPs, with a Gaussian profile for UV-Vis spectra was obtained, with an hour centrifuge process.
- The life time of SERS substrates was investigated. SERS signals gathered after one month showed exceptional compatibility.
- SERS intensities obtained 0.72 to 1 ratio uniformity throughout samples which is a promising for unification of SERS.
